Tillage Sequence

Understanding tillage sequences is critical for good soil and bed preparation prior to spring planting. Ill-timed or poorly executed tillage will lead to frustration and soil cloddiness. This is especially true for more challenging soils higher in clay content. The specific sequences you use will depend on soil type and implement selection.

Here are two examples of common tillage and bed formation sequences used on California’s Central Coast. One uses a mechanical spader to incorporate cover crop residue, the second an offset disc.

Spring incorporation of cover crop residue and bed formation

TOOLS: flail mower, mechanical spader, rolling cultivator

- Flail mow cover crop at appropriate soil moisture to minimize compaction. With a tall cover crop (3–4’ or more), do an initial “high mow” pass with the mower set 1–2’ above the ground, then mow at ground level to further chop and shred the crop into small pieces prior to incorporation to facilitate the breakdown process.

- Immediately after flail mowing cover crop, use a spader to incorporate residue.

- Immediately after spader incorporation of cover crop, form beds with rolling cultivator.

- Allow adequate time for breakdown of cover crop residue. If rainfall is not adequate after bed forming then pre-irrigate to maintain enough moisture to facilitate residue breakdown.

- Shortly after weed emergence re-work the beds with rolling cultivator.

Beds are now ready for shaping and planting.
Bed Shaping

Once beds are raised with either listing shovels or a rolling cultivator (Figure 1), and assuming optimum tilth has been achieved through well-timed tillage, you can use a “bed shaper” to shape a bed suitable for precision seeding (e.g., carrots, beets), or multi-line transplanting (e.g., lettuce, brassicas), and follow-up weed management.

Bed Shapers are three-point implements that run behind the tractor and flatten out the bed top, providing a smooth, uniform, and well-defined bed for planting. Vegetable seeders can be attached directly to the shaper so that beds can be shaped and planted in one pass. Markers can also be attached to the shaper to provide distinct lines for transplanting (Figure 2).

Planting to Moisture

This often-overlooked planting technique is an effective way to minimize weed competition when planting large-seeded crops such as beans, squash, and some cover crops, especially in California’s Mediterranean climate. Potatoes and dry-farmed tomatoes can also be planted to moisture. Here is a suggested sequence (Figure 3):

<tr>
<td>Do first cultivation with sweeps, knives, reverse disc hillers. Lay drip lines.</td>
</tr>
<tr>
<td>Do second cultivation with rolling cultivator to reform beds</td>
</tr>
</tbody>
</table>
**Step 1: Pre-irrigation**

When planting to moisture –
- Form beds prior to planting (see above)
- Pre-irrigate with drip or overhead irrigation to flush weed seeds and get deeper moisture into the root zone. Apply approximately 1–1.5” on most soils, assuming there is good moisture deep in the soil either from irrigations on previous crops or from winter rains.
- If water is limited, drip can be used to pre-irrigate, but drip lines must then be retrieved before planting.
- On rare occasions, a well-timed rain event of an inch or more can provide adequate moisture to flush weeds.

**Step 2: Initial cultivation of fallow (unplanted) beds**

Once you see weeds emerge on the beds and in the furrows (about a week after pre-irrigation), make a quick pass with a cultivating implement such as a rolling cultivator to knock out the newly emerged weeds (Figure 4) and newly germinated weed seeds that have not yet emerged. This pre-emergent weed growth stage is referred to as “white thread,” because the radical (first root) of the newly germinated weed seed literally looks like a white thread. At this stage of growth weeds are extremely susceptible to light cultivation. Avoid deeper cultivation, as this would bring up new weed seeds from lower in the soil that have not yet germinated.

Note that the “fallow bed” cultivation following pre-irrigation must be timed well to minimize tractor tire soil compaction from soil that is too wet in the furrow bottoms. Timing is critical as well in terms of the maturation level of the emerged weeds: once true leaves are formed on many weed species they can become much more difficult to terminate/kill when relying on mechanical cultivation. This is especially true for purslane.

**Step 3: Planting to moisture**

For beans, winter squash seeds:

When planting to moisture, the bed top must be mechanically knocked off so that the planter can place seeds into moist soil. This operation is most efficiently done with a wide “Alabama” shovel mounted on the planter to run ahead and push off the dry dirt on top of the bed (Figure 5). When set correctly, the shovel should leave a flat “V” pattern down the center of the bed. At the bottom of the “V” the soil should contain adequate residual pre-irrigation moisture (or rain moisture) to initiate germination of the newly planted seed.

Planting beans and winter squash seed at the low point in the middle of the bed will conserve moisture deeper in the soil because there is still a lot of loose soil above the seed line, limiting evaporative loss of soil moisture. Planting large-seeded crops to moisture also minimizes the risk of soil borne pathogens (damping off complex) that can affect their development. Damping off is more likely to occur when seeds are “irrigated up” with either overhead irrigation or drip irrigation.
For dry-farmed tomatoes:

Use an Alabama shovel as described above to create a V-shaped furrow. Hand-plant well-hydrated tomato starts deep into moist soil (Figure 6).

For potatoes:

Drop the seed pieces into a depression or trough formed by an Alabama or furrowing shovel (Figure 7), and cover with 3–4” of soil (enough to cover the seed pieces and keep them from drying out) by pushing some of the soil pushed off the bed top back into the middle of the bed.

When the potatoes are tall enough (8–12”) make a second pass with a rolling cultivator, reverse disc hillers, or shovels to re-form the bed. This process is referred to as “hilling” and will ensure that the potatoes are adequately covered with soil to minimize sun damage.
